Table 2: Summary of max linear probe accuracy by SSL Method and Augmentation. Maximum value across 4 seeds. Best result for KNN and SVM are highlighted in bold.

From the tables we see a significant improvement in probe accuracy with NC-VQVAE compared to naive VQVAE. Some configuration is best on 12 out of 13 datasets. The one where our model falls short, the difference is one percent for both svm and knn. The largest differences are seen on FordA, FordB, Mallat, ShapesAll, TwoPatterns and UWaveGestureLibraryAll. On ShapesAll and TwoPatterns the difference is around 0.30 to 0.40.

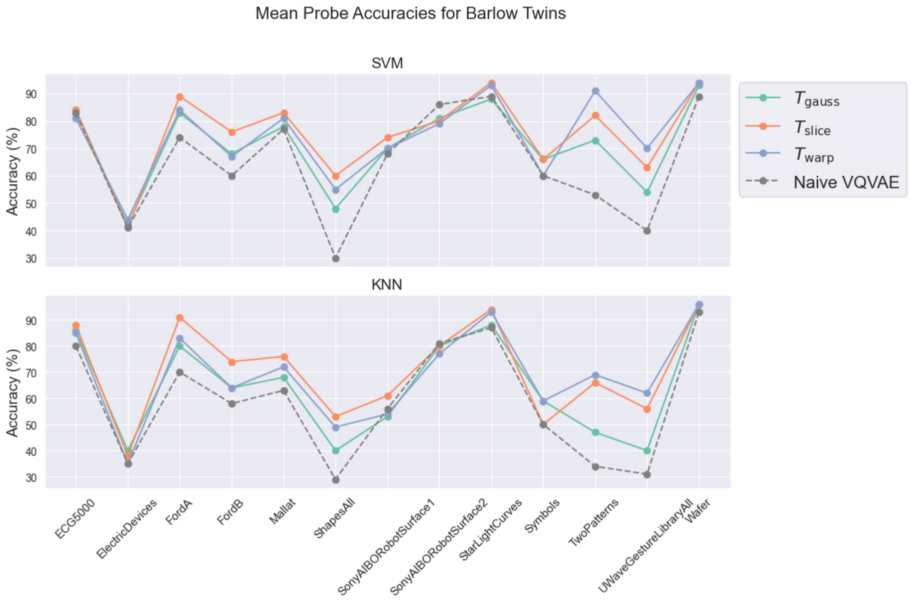

Figure 3: Mean probe accuracies for Barlow Twins VQVAE

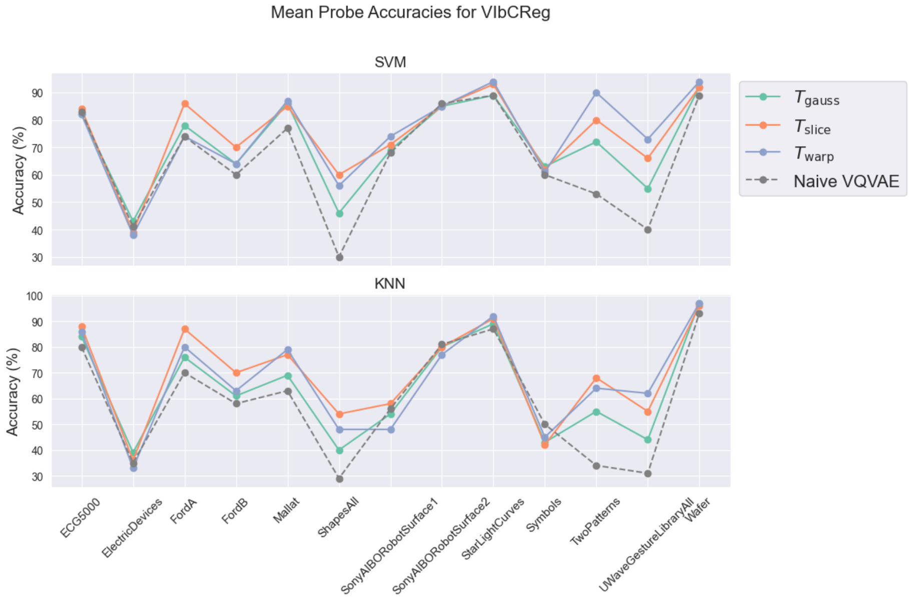

Figure 4: Mean probe accuracies for VIbCReg VQVAE

How does augmentations influence probes?

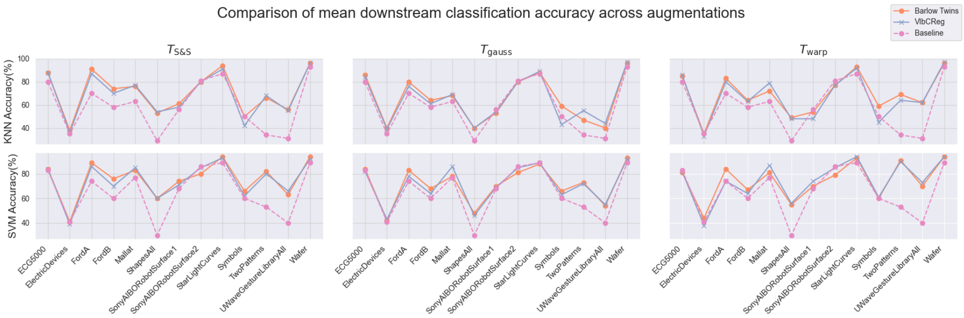

Figure 5: Comparison of mean downstream classification accuracy across augmentations

SSL loss during training. Gauss is much easier to minimize. Probes seem to be better for warp and slice.

The NC-VQVAE model is able to reconstruct on par with naive VQVAE, and in some cases improve the reconstruction loss, while significantly improving the probe accuracy for the discrete latent representations for most datasets. The NC-VQVAE produces representations that separates classes more effectively, and could in turn encode more class specific information.

Table 4: Summary of FID and IS scores by SSL Method and Augmentation. Best mean achieved FID and IS are highlighted in bold

From the table we see that our model produces better IS score for 12 out of 13 datates, and better FID for 10 out of 13.

In the visual inspection section we illustrate that lower FID not always correspond more realistic synthetic samples, and that out model often capture the conditional distributions better than naive VQVAE.

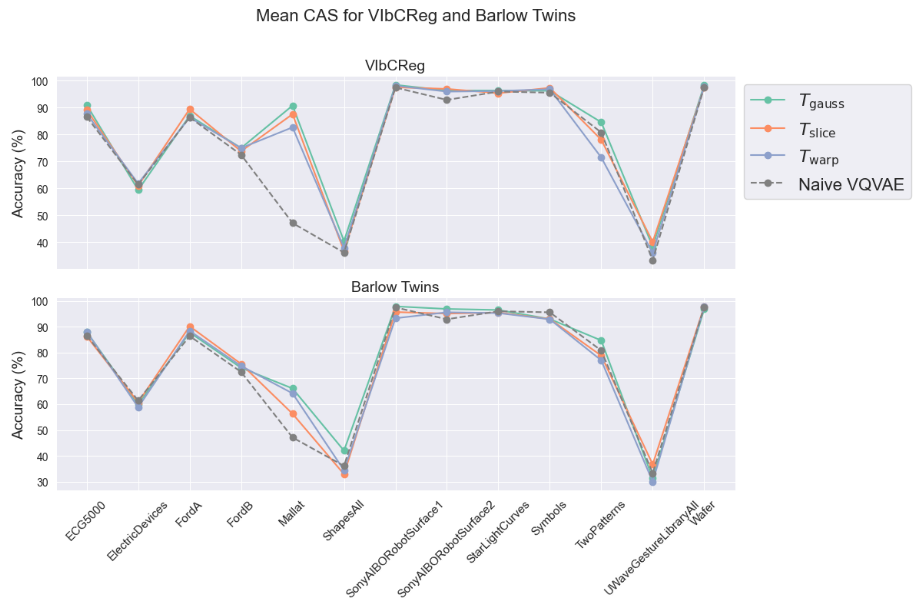

Figure 8: Mean probe accuracies for VIbCReg VQVAE

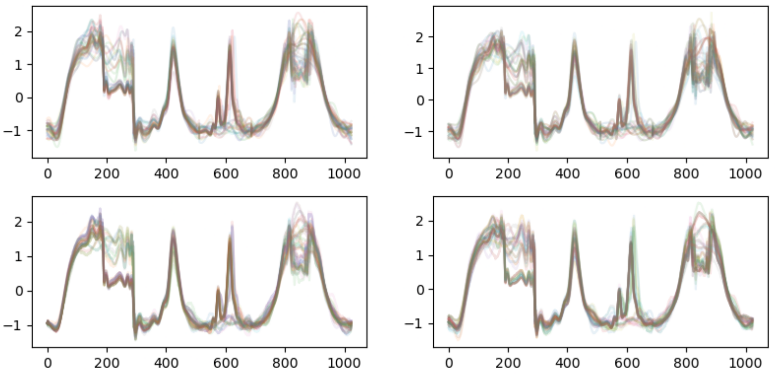
TODO: Plots that illustrate.



Naive VQVAE.
Real (Top) vs synthetic (Bottom)

VIbCReg with Gaussian augmentation. Real (Top) vs synthetic (Bottom)

Figure 9: Difference in synthetic samples between the top performing naive VQVAE and VIbCReg VQVAE with Gaussian augmentation. The VIbCReg VQVAE samples are more varied in the first 300 timesteps, which from figure **??** contains much class specific information.

0.2.3 Prior loss

Mention that during experiments with our stage 2 modification, embed / finetune, we observed that the val prior loss with our modification was higher, but with similar shape as without. If we had time and computational resources to rerun the experiments, then we would omit the stage 2 modification. The FID/IS in our main experiments are in many cases better than baseline VQVAE, despite higher val prior loss.

0.2.4 Visual inspection

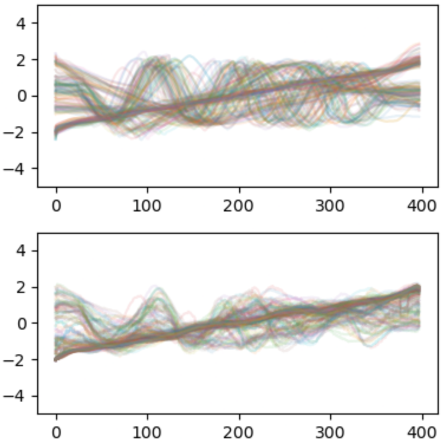
Symbols

Naive VQVAE: Does not capture the entire underlying distribution, some classes are not represented/not recognizable. Global consistency for the sinusoids are poor, particularly towards the end.
VIbCReg: Good mode coverage, but underrepresents the sinusoids or lacks diversity in each class.

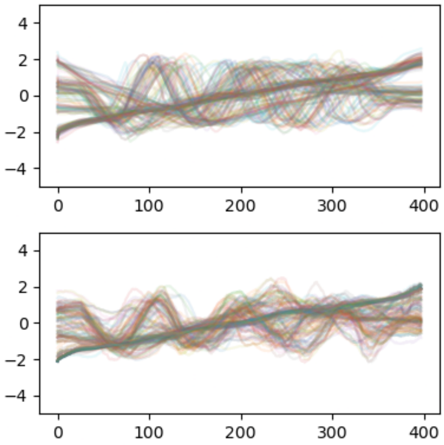
Barlow Twins: windowwarp: little variability in sinusoids, could it be that the ssl loss makes these too close in latent space?

Does the high IS scores correlate with good mode covarage? For symbols our model cover the modes much better than naive. But produces many very similar samples. Does this have something to do with the selected token histograms. Seems like our models select tokens with higher probability, sometimes much higher!

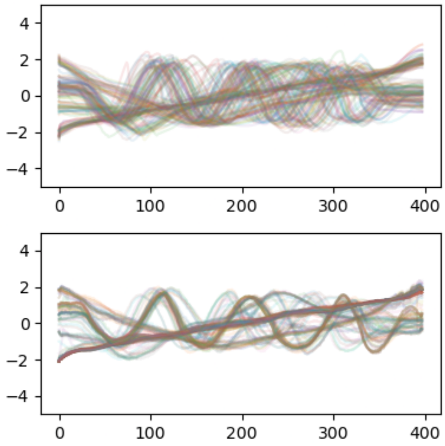
IS has a flaw in that it does not take intraclass diversity into account. Thus a model which generates the mode at each class will get a high IS score. Thus it can give high scores to models that overfit.



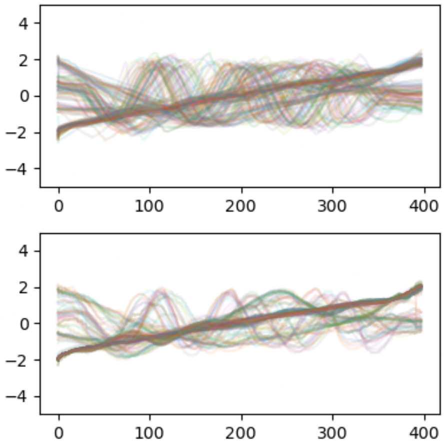
Collapse of global consistency for Naive VQVAE



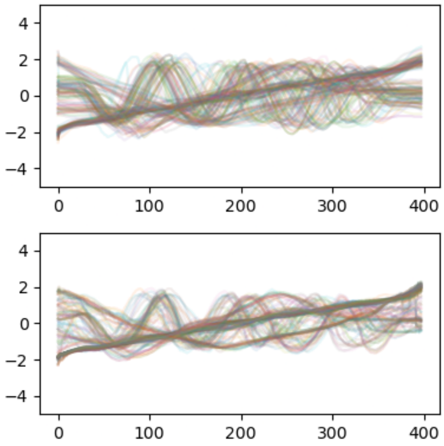
Best Naive VQVAE in terms of FID and IS



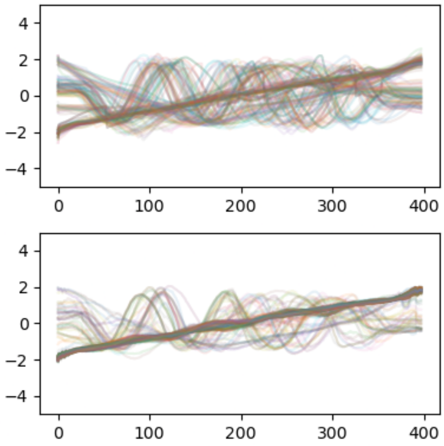
Barlow Twins with Gaussian augmentation, the best performing BT model in terms of FID and IS



Barlow Twins with Gaussian augmentation, the wors performing BT model in terms of FID.



VIbCReg with Slice and Shuffle augmentation, the best performing BT model in terms of FID. Among top performers in terms of IS



VIbCReg with Slice and Shuffle augmentation, the worst performing VIbCReg model in terms of FID and IS.

Sony2 is interesting

ShapesALL

A LOT BETTER class conditional sampling!

Generated vs real.

UWaveGestureLibraryAll

Our model follows the training data quite closely. It might be susceptible to generate outlier data.

The bias introduced by augmentation

MaskGIT more certain of tokens

look at selected token histograms. Seems like our models select tokens with higher probability. Would be interesting to investigate different values for T in maskgit iterative sampling.

0.3 The influence of stage 1 on stage 2

The best performing datasets in terms of probe accuracies: "FordA", "FordB", "Mallat", "ShapesAll", "TwoPatterns", "UWaveGestureLibraryAll"

Relationship between reconstruction in stage 1 and FID/IS/CAS: Does better reconstruction capabilities in stage 1 improve the generative model?

Relationship between probes in stage 1 and FID/IS/CAS: Does better probe accuracies (class separation) in stage 1 improve the generative model?

How does the best performing models from stage 1 transfer to stage 2?

Look at FordA, FordB, Mallat, ShapesALL, TwoPatterns and UWaveGestureLibraryAll. The datasets where probe accuracies are good compared to baseline. Slice is aug with best performance overall on these datasets.

0.3.1 Thoughts

Better inception score and CAS of our models indicate that the class separability learned in latent space makes the conditional distributions more distinct easier to classify. The FID is variable, but in many cases better, which indicated that the generative distributions are closer to the ground truth.

Gaussian noise aug seems to result in a lot easier the BT/VIbCReg loss to minimize.
Slice and shuffle is harder to minimize, but could seem to push representations for different classes further apart resulting in better linear probes.

Talk about the difficulty/ease in minimizing the SSL loss for the different augmentations. Does this affect linear probes / reconstruction / FID / IS / Prior loss

For datasets of smaller size with classes of different characteristics (a clear distributional difference in visual inspection [Sony2 and Symbols]) NC-VQVAE seems to perform better both in terms of FID and IS.

The biases introduced by augmentations in stage 1 seems to be included in the generated samples to some degree. In particular datasets with high frequency components, when applying Gaussian noise (easier to spot), has substantially better FID score.

Is there correlation between CAS and linear probe accuracy??

Temporal vs frequency influence of augmentations. We compress only along temporal axis in the encoder. Could this be a reason for Gaussian artifacts in generation and not slice?

0.4 Discussion

The added flexibility of NC-VQVAE, with possibility of choosing dataset specific augmentations, can in some applications be beneficial.

0.5 Further work

[**morningstar2024augmentations**] suggest that focus on augmentations is of great importance. The hunt for good augmentations in the time series domain is ongoing and should probably get more attention.
HF-LF split - augmentations tailored for HF and LF, as they often have quite different characteristics.
Wavelet transform to improve HF-LF split.

Further optimize the relationship between aug recon loss and choice of augmentations.
